# ARCHAEOASTRONOMY

Thom was professor of Science and Engineering at Oxford from 1946 – 1961. Megalithic remains became an interest in the early '30s; initially stone 'circles' but later declinations from stones and other possible backsights. He produced evidence that a 16 month solar calendar existed and that the small variation in lunar declinations at the 'standstills' had been observed. This last would have enabled eclipse predictions.

Indicated direction  
about  $\pm 2^\circ$

## An Alignment giving high accuracy

An orientation of about  $\pm 2^\circ$  .....

..... can become an alignment capable of 1' of arc precision.

An horizon region indicated by a backsight with a typical precision of about  $\pm 2^\circ$ . (Foresights are discussed later.)

## Chance alignments

Ruggles has written that in hilly country from an arbitrary point:-  
“ ...the chances are that we could find at least one or two horizon features interpretable as lunar foresights.”

This possibility was checked in the field:-

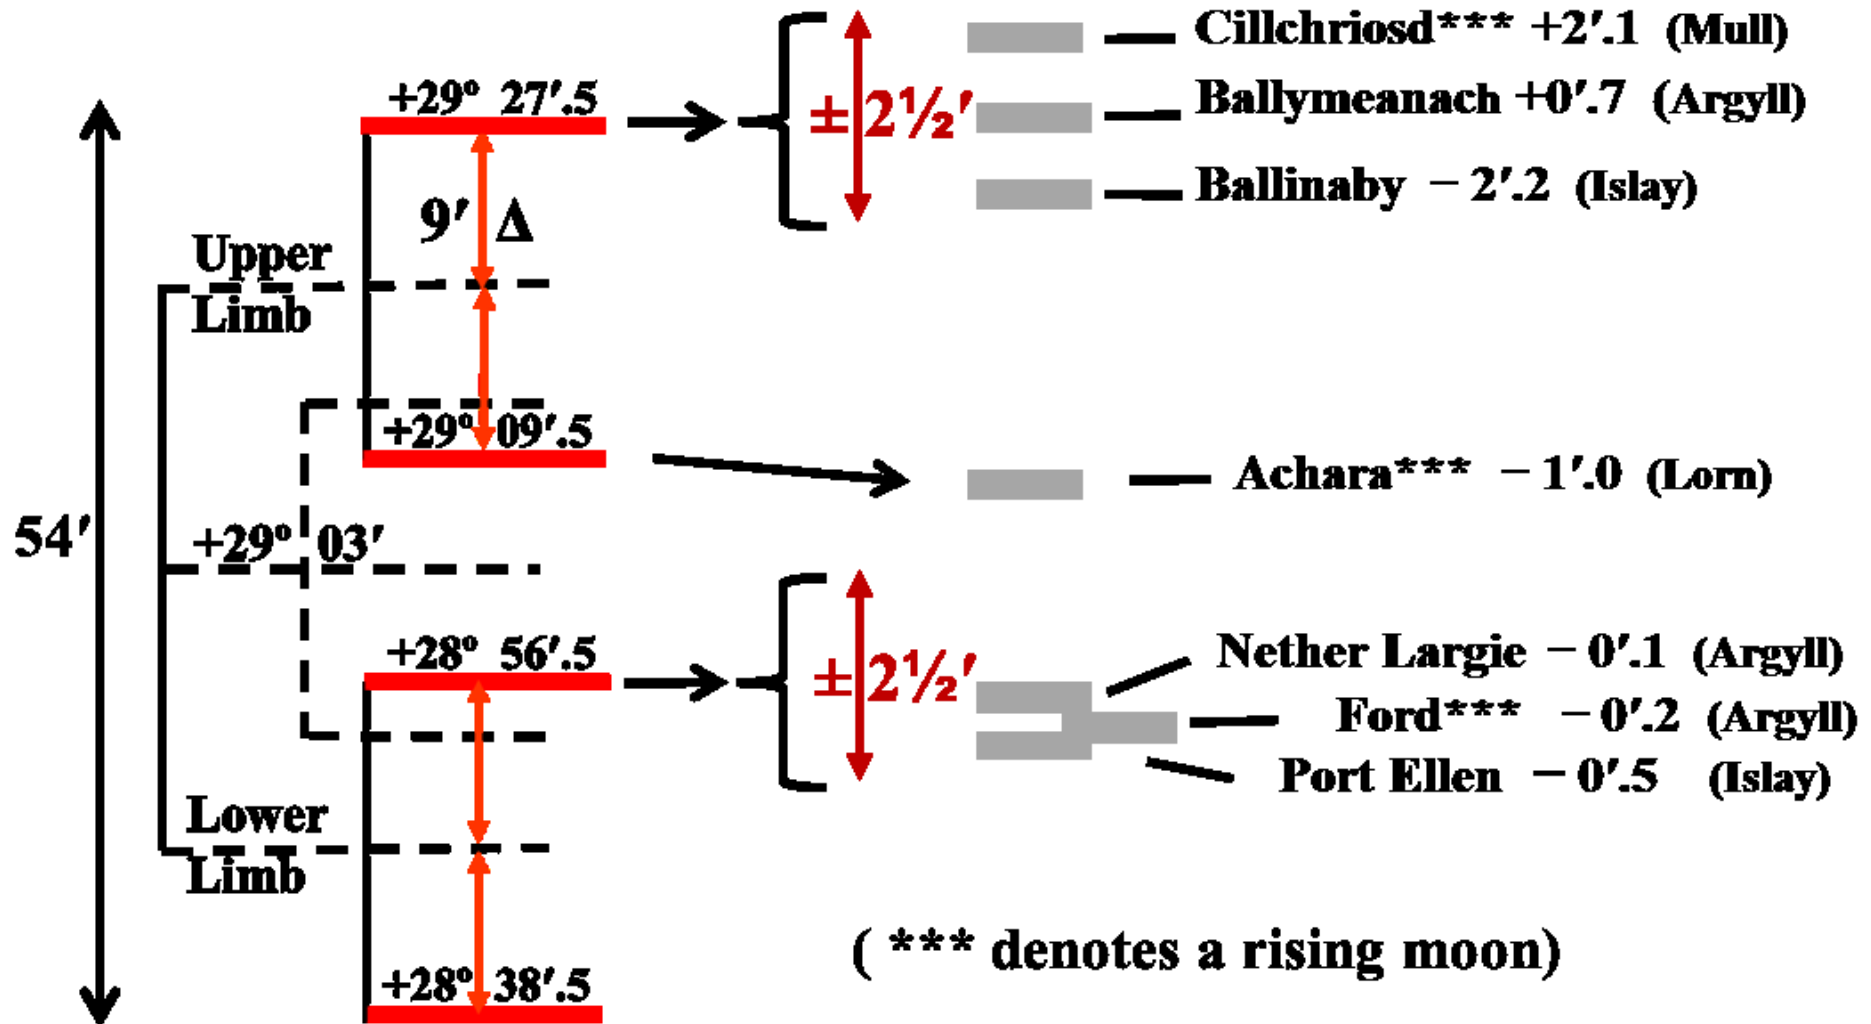

From 10 identifiable places with suitably hilly skylines, usually at a stone, a search for chance alignments was made.

In total some 1500 degrees of hilly horizon was searched. This contained 30 lunar bands. Three chance alignments were found; two minor alignments and one major alignment.

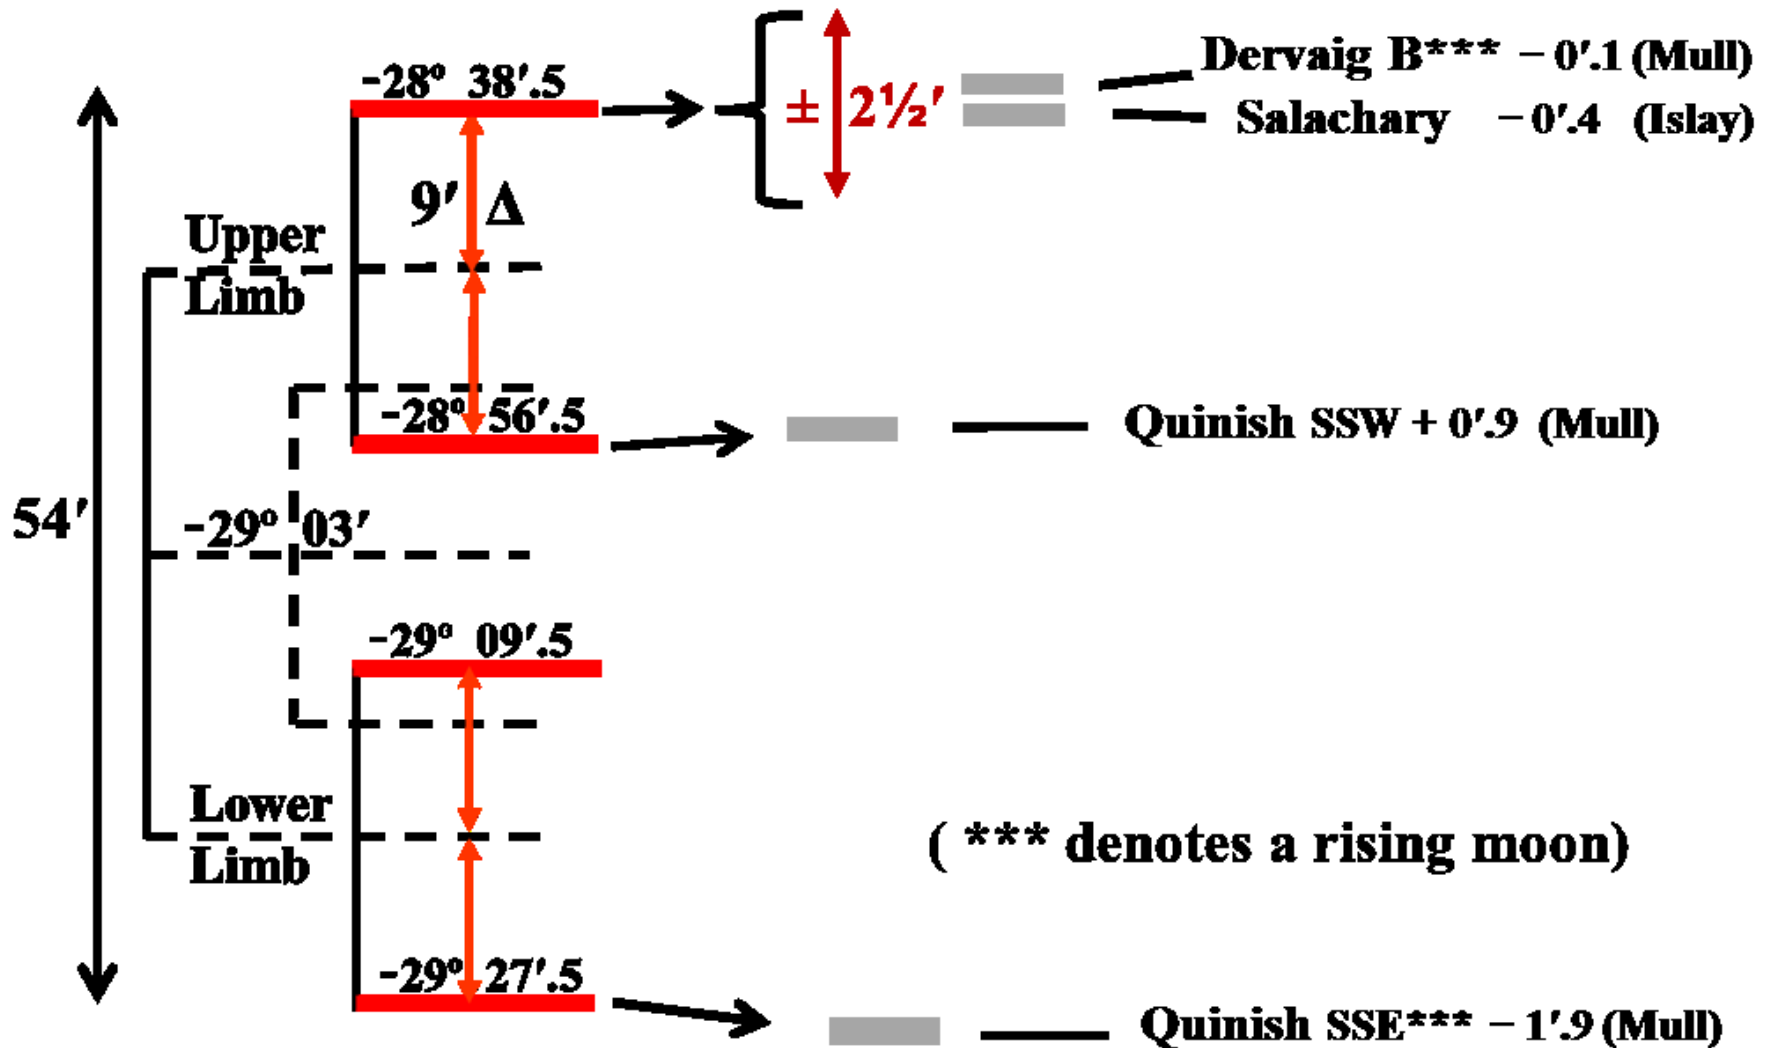

Thus in this study 1 in 10 chance alignments were found which cannot explain the results found.

# The 7 precise alignments at the Lunar Standstill North

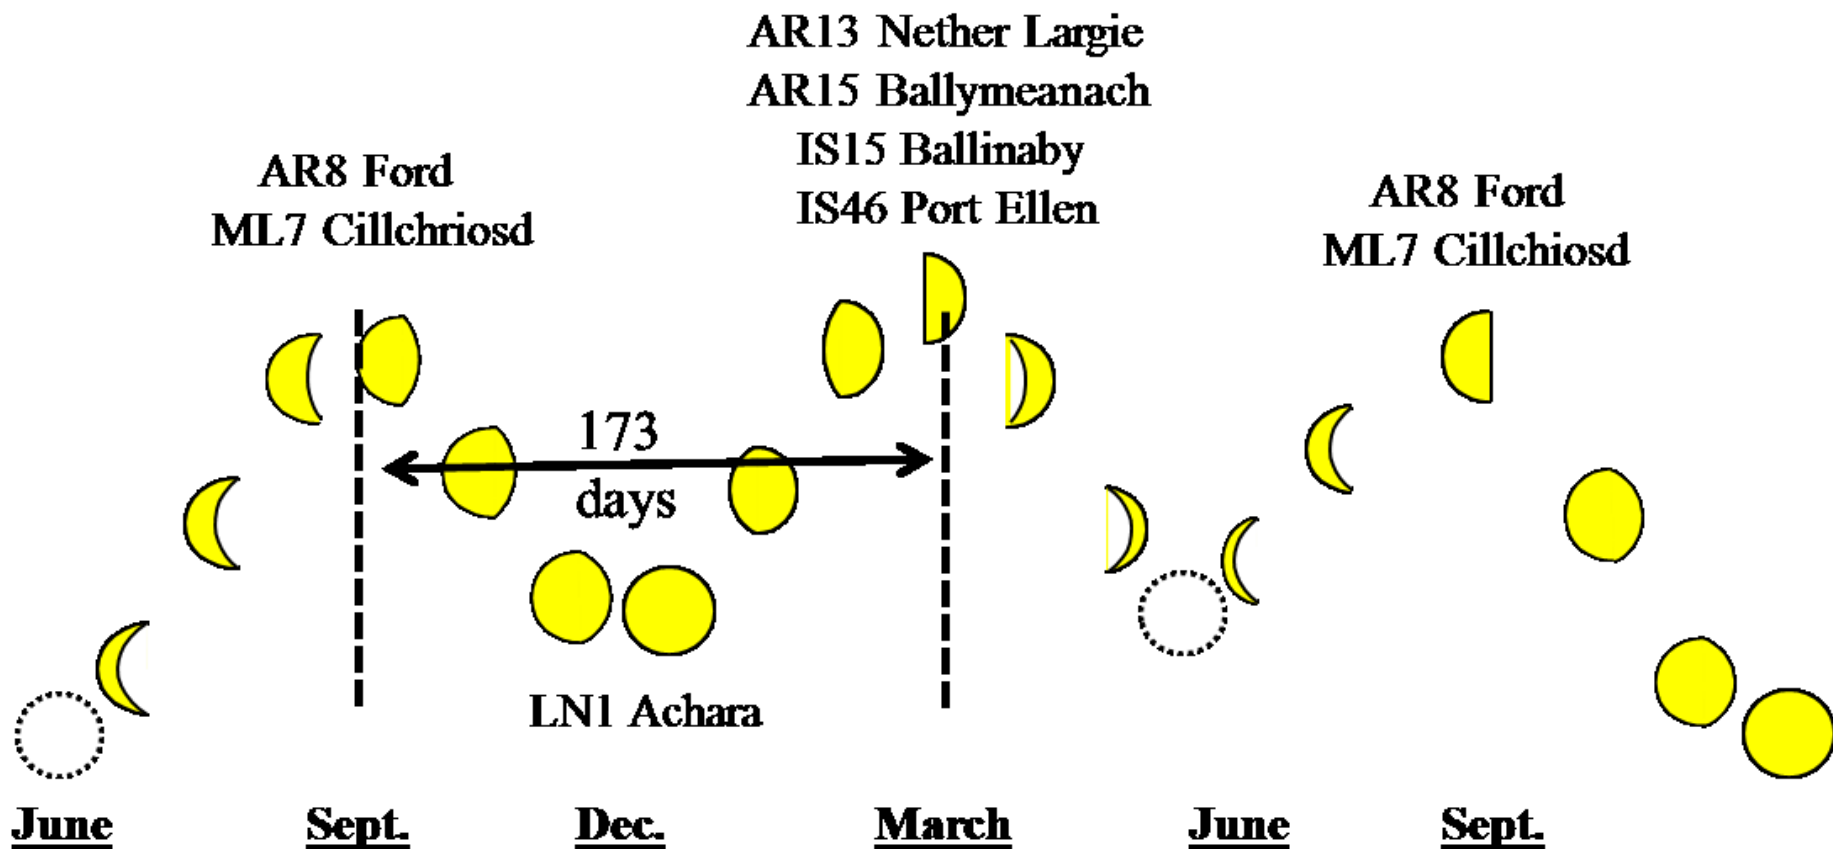

# The 4 precise alignments at the Lunar Standstill South

# Maximum Standstill North (Typical)

(Note: Size of moon much reduced for clarity)

## Rate of Moon movement near maximum

# Apparent Lunar Alignments for the 'no Wobble' Moon

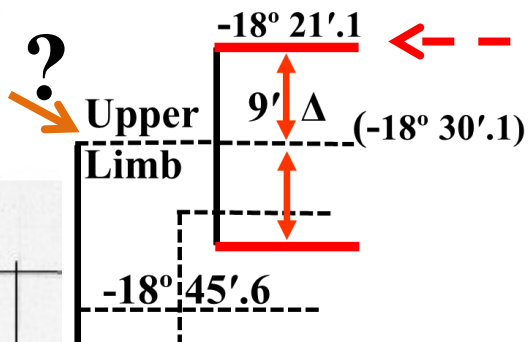

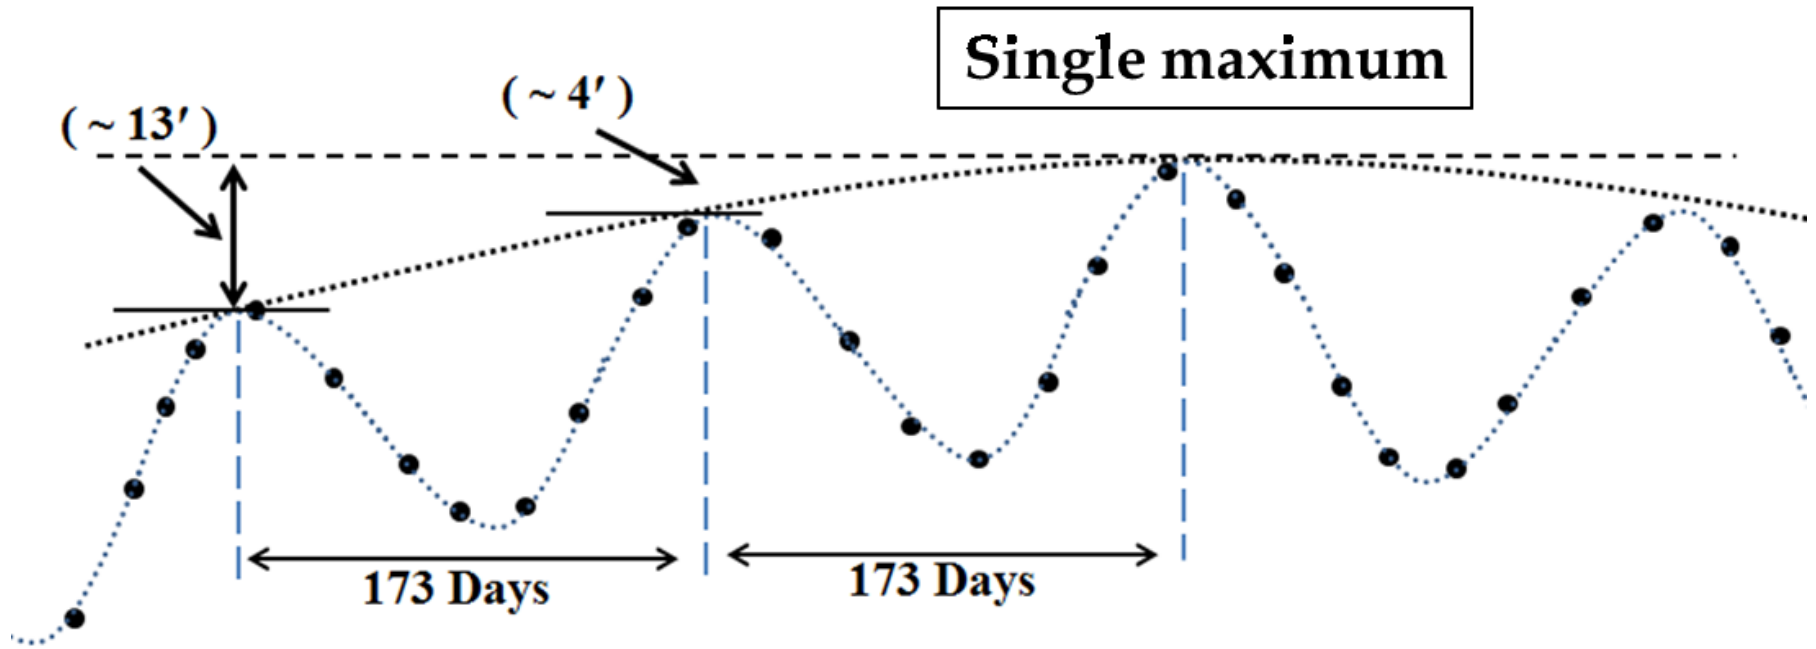

View to SW

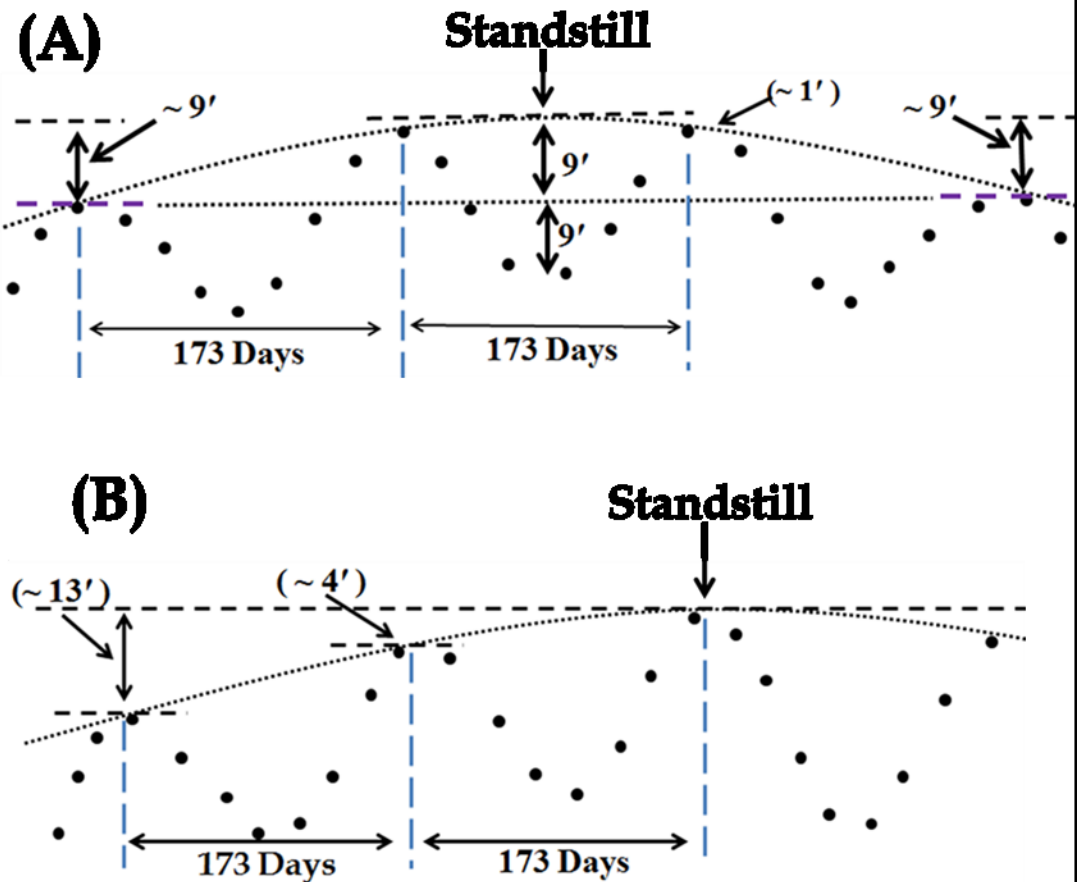

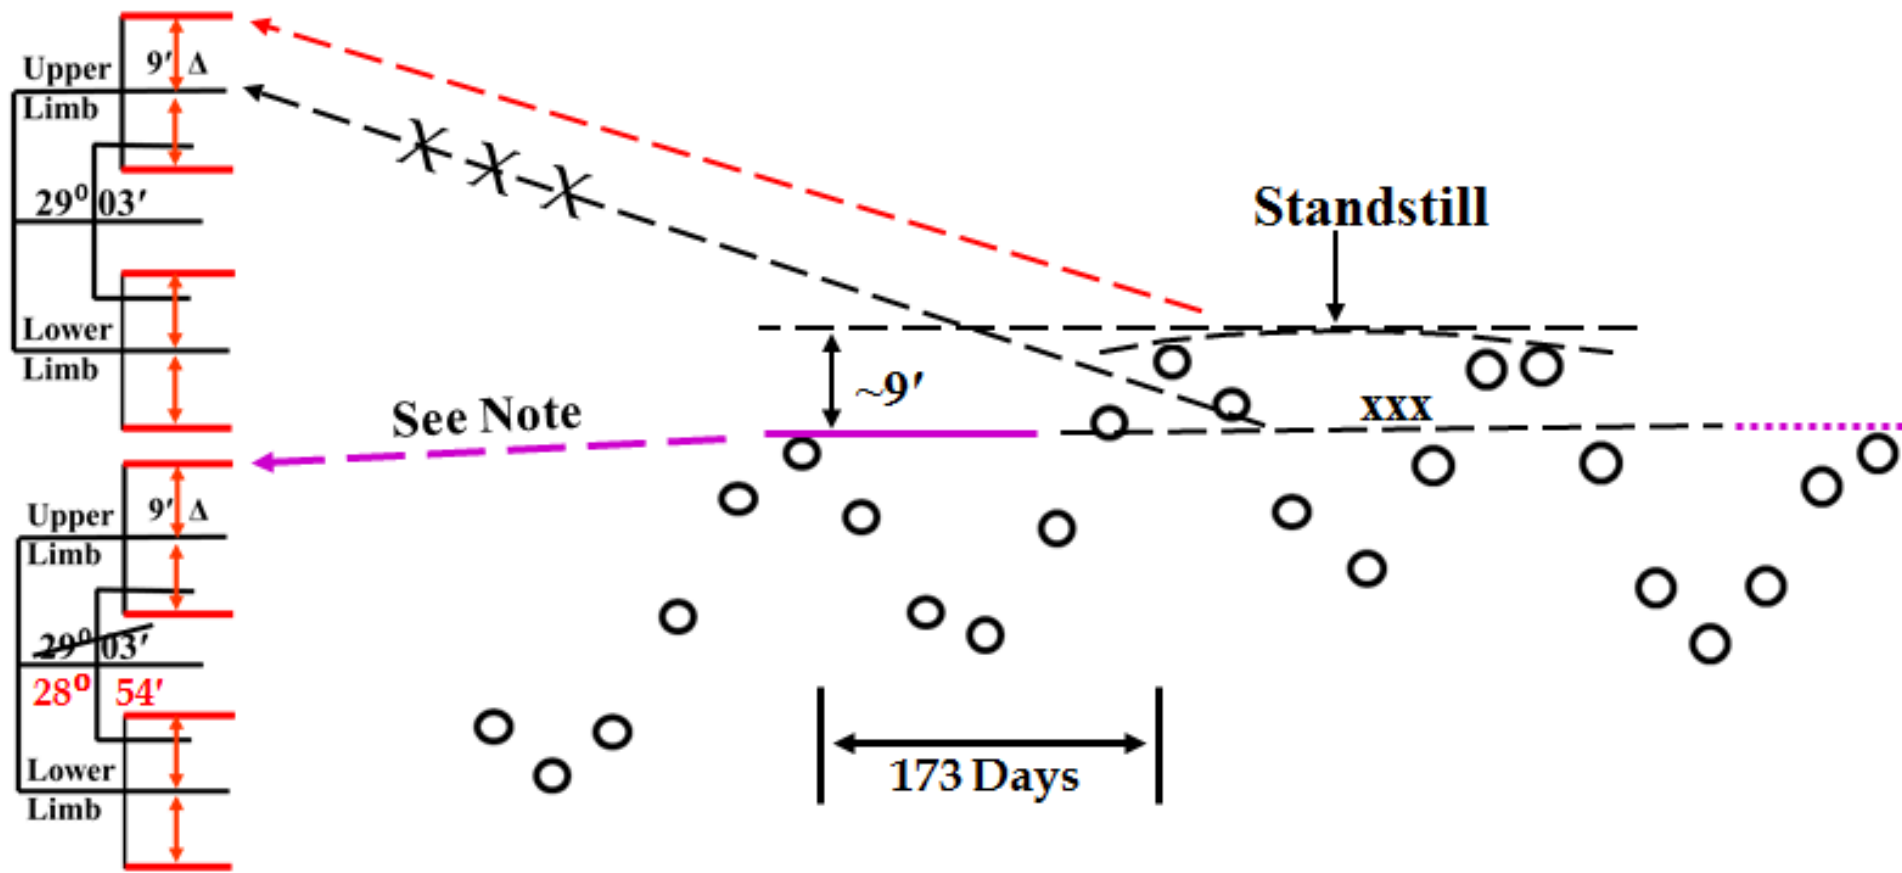

The Standstill might be as in (A) with two maxima, or (B) with a single maxima or anywhere in between. Note in (A) the deficit of 9' of arc of the maxima 1½ ecliptic periods before the standstill maximum i.e. by chance the 'wobble' amount.

In (B) the values are as shown.

Thus a possible explanation is that the observation of what we have deemed the 'no wobble' alignment was actually for the maxima of a preceding wobble to enable prediction of the type of maxima to be expected.
