

could be taken into account for each night by scaling the moonlit sky surface brightness by this fraction to give a weighted background for the night, but on balance it is considered better to partition telescope time solely in terms of the *worst case* sky surface brightness computed $\sim 90^\circ$ from the Moon.

The predicted ranges in the zenith V sky surface brightness at high galactic and ecliptic latitudes, and solar minimum, and at an angular distance from the Moon of $\sim 90^\circ$, are 21.2–21.9 mag/arcsec² for dark time, and 19.9–21.2 and 18.0–19.9 mag/arcsec² respectively for the *moonlit parts* of grey and bright time. For the mean sky, i.e. over all latitudes $\sim 90^\circ$ from the Moon, these ranges are ~ 0.5 mag/arcsec² *brighter* because of the larger contributions of airglow, zodiacal light and starlight.

This definition of dark, grey and bright time will be used in constructing the ING schedules from Semester 2002B onward. The exposure time calculator,

SIGNAL, has been modified to offer an option specifying 'typical' sky surface brightnesses for dark, grey and bright time, corresponding to $V_{sky}=21.50, 19.75$ and 18.50 mag/arcsec² respectively.

A longer version of this article is available as *ING Technical Note No. 127*, available at URL http://www.ing.iac.es/Astronomy/observing/manuals/man_tn.html
